

E-Unification AC-Unification

ChuChen

E-Unification

- A fixed set of identities E :
 given terms s and t , find a substitution σ such that $\sigma(s) \approx_E \sigma(t)$. This substitution is called an E -unifier of s and t .

For example: syntactic unification $E = \emptyset$.

For example: assume that E implies that the binary function symbol f is commutative.

$$f(x,y) \approx_E f(y,x).$$

Example

- $S = \{f(x, y) =? f(a, b)\}$

The substitution $\sigma := \{x \rightarrow b ; y \rightarrow a\}$ is not a syntactic unifier of S

However it is a E-Unifier of S , since

$$f(b, a) \approx_E f(a, b).$$

Definition

- An E-Unification problem over Σ is a finite set of equation $S = \{ s_1 \approx_E t_1, \dots, s_n \approx_E t_n \}$ between Σ -terms with variables in V . An E-unifier or E-Solution of S is a substitution σ such that $\sigma(s_i) \approx_E \sigma(t_i)$ for $i=1, 2, \dots, n$. The set of all E-Unifiers of S is denoted by $\ddot{U}_E(S)$ and S is called E-unifiable if $\ddot{U}_E(S) \neq \emptyset$.

E-Unification

- $\text{Sig}(E)$ denotes the signature of E , i.e. all the function symbols occurring in E .
- And let Σ be a signature that contains E .
- S is an elementary E -unification problem iff $\text{Sig}(E) = \Sigma$
- S is an E -unification problem with constants iff $\Sigma - \text{Sig}(E)$ consists of constant symbols.
- In a general E -unification problem, $\Sigma - \text{Sig}(E)$ may contain arbitrary function symbols.

The Order

- Let X be a set of variables. A substitution σ is more general modulo \approx_E than a substitution σ' on X if there is a substitution δ such that $\sigma'(x) \approx_E \delta(\sigma(x))$ for all $x \in X$. In this case we write $\sigma \leq_e^X \sigma'$. We also say that σ' is an E-instance of σ on X .

Complete Set

- Let S be a E-Unification problem over Σ and let $X := \text{Vars}(S)$. A complete set of E-Unifiers of S is a set of substitutions ζ that satisfies :
- Each $\sigma \in \zeta$ is an E-unifier of S
- for all $\theta \in \ddot{U}_E(S)$ there exists $\sigma \in \zeta$ such that $\sigma \leq_E^X \theta$.

Minimal Complete Set

- A minimal complete set of E-unifiers is a complete set of E-unifiers M such that for all $\sigma, \sigma' \in M$, $\sigma \leq^x_E \sigma'$ implies that $\sigma = \sigma'$

Example: $C := \{ f(x,y) \approx f(y,x) \}$

$S := \{ f(x,y) \approx_c f(a,b) \}$

$\sigma_1 = \{ x \rightarrow a, y \rightarrow b \}$ and $\sigma_2 = \{ x \rightarrow b, y \rightarrow a \}$

Mapping Between the Minimal

- Assume that M_1 and M_2 are minimal complete sets of E-unifiers of S . Then there exists a bijective mapping $B : M_1 \rightarrow M_2$ such that $\sigma_1 \sim_E^x B(\sigma_1)$ holds for all $\sigma_1 \in M_1$

Unification Type

- **Unitary:** iff a minimal complete set of E-unifiers exists for all E-Unification problems S with cardinality ≤ 1 .
- **Finitary:** iff a minimal complete set of E-unifiers exists for all E-Unification problems S with finite cardinality .

Unification Type

- **Infinitary:** iff a minimal complete set of E-unifiers exists for all E-Unification problems S , and there exists an E-Unification problem for which this set is infinitary.
- **Zero:** iff there exists an E-Unification problem that does not have a minimal complete set of E-unifiers.

AC-Unification

- The equational theory induced by the set of identities :

$$AC := \{(x * y) * z \approx x * (y * z), x * y \approx y * x\},$$

which axiomatizes the associativity and commutativity of a single binary function symbol $*$.

AC1-Unification

- It is more convenient to start with unification modulo the theory induced by $AC1 := AC \cup \{x^*1 \approx x\}$
- $\Sigma_1 = \Sigma \cup \{1\}$ for a constant symbol 1.
- The infinite set of variables $V := \{x_1, x_2, \dots, x_n\}$
- The module symbol $\approx_{AC} \rightarrow \approx_{AC1}$
- $T(\Sigma_1, V)$

Lemma

- The number of occurrences of the variable x in the term t is denoted by $|t|_x$.
- Lemma: Let $s, t \in T(\Sigma_1, V)$

$$s \approx_{AC1} t \text{ iff } |s|_x = |t|_x \text{ for all } x \in V.$$

Proof \Rightarrow by induction on the number of rewriting steps to transform s to t .

$$\Leftarrow s \approx_{AC1} X_1^{k1} \dots X_n^{kn}, t \approx_{AC1} X_1^{l1} \dots X_n^{ln}$$

Vector

- Given a finite set $X_n := \{x_1, x_2, \dots, x_n\}$
 $s \in T(\Sigma_1, X_n)$ is uniquely determined by vector
 $V_n(s) = (|s|_{x_1}, |s|_{x_2}, \dots, |s|_{x_n})$;
- Lemma:
Let $s, t \in T(\Sigma_1, X_n)$.
(1) $s \approx_{AC1} t$ iff $V_n(s) = V_n(t)$ iff $s \approx t$.
(2) $V_n(s) \in \mathbb{N}^n - 0$

Equation

- Let $n, m \geq 0, s \in T(\Sigma_1, X_n)$
 σ is a substitution and $\sigma(x_i) \in T(\Sigma_1, X_m)$,
given $V_n(s)$ and $V_m(\sigma(x_i))$ for all $x_i \in X_n$ we
can compute $V_m(\sigma(s))$:

$$| \sigma(s) | = \sum_{i=1}^n | s |_{x_i} | \sigma(x_i) |_{x_j}$$

The Matrix

- $M_{n,m}(\sigma)$ denotes the $n \times m$ matrix whose rows are vectors $V_m(\sigma(x_i))$.

$$\begin{array}{ccc} |\sigma(x_1)|_{x_1} & \dots\dots & |\sigma(x_1)|_{x_1} \\ \dots\dots & \dots\dots & \dots\dots \\ |\sigma(x_n)|_{x_1} & \dots\dots & |\sigma(x_n)|_{x_m} \end{array}$$

Lemma

- Lemma:

$$V_m(\sigma(s)) = V_n(s) \cdot M_{n,m}(\sigma).$$

Example:

$$s := x_1^2 * x_2 \quad \sigma := \{x_1 \rightarrow x_2 x_3, x_2 \rightarrow x_1^2 x_3\}$$

then

$$V_2(s) = (2,1)$$

$$\sigma(s) = (x_2 x_3)^2 x_1^2 x_3 \approx_{AC} x_1^2 x_2^2 x_3^3 \mid$$

Lemma

$$M_{2,3}(\sigma) = \begin{pmatrix} 0 & 1 & 1 \\ 2 & 0 & 1 \end{pmatrix}$$

$$V_3(\sigma(s)) = (2,2,3) = (2,1) \cdot \begin{pmatrix} 0 & 1 & 1 \\ 2 & 0 & 1 \end{pmatrix}$$

AC1-Unification Problem

- An elementary AC1-unification problem:
 $S := \{ s_1 \approx_{AC1} t_1, \dots, s_n \approx_{AC1} t_n \}$ $X_n := \{x_1, \dots, x_n\}$ be the set of all variables occurring in S , let σ be a substitution and there exists $m \geq 1$ such that $\sigma(x_i) \in T(\Sigma_1, X_m)$ for all $x_i \in X_n$.
- Lemma:
 - σ is a AC1-unifier of S
 - $$V_n(s_i) \cdot M_{n,m}(\sigma) = V_n(t_i) \cdot M_{n,m}(\sigma) \quad \text{for all } i=1 \dots n$$

DE(S)

- Let $M_{k,n}(S)$ be the integer matrix whose rows are the vectors $V_n(s_i) - V_n(t_i)$ i.e. the matrix whose entry at position (i,j) is $|s_i|_{x_j} - |t_i|_{x_j}$
K denotes the cardinality of problem set S.
- σ is an AC1-unifier of S iff the columns of $M_{n,m}(\sigma)$ are (no-negative integer) solutions of the system of
homogeneous linear Diophantine equations

DE(S)

$$M_{k,n}(S) \cdot \begin{pmatrix} y_1 \\ \dots \\ \dots \\ y_n \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

finite generating set

- Let $M_{k,n}$ be a $k \times n$ integer matrix, and let

$$M_{k,n} \cdot y = 0 \quad (*)$$

be the system of homogeneous linear Diophantine equations induced by $M_{k,n}$

- A finite set $V = \{v_1, v_2, \dots, v_n\}$ is a generating set for the set of all solutions of (*) iff every element of V solves (*) and for each $v \in \mathbb{N}^n$ that solves (*) there exist $a_i \in \mathbb{N}$ such that

$$v = v_1 \cdot a_1 + \dots + v_r \cdot a_r$$

Finite Generating Set

- A finite generating set $W := \{v_1, \dots, v_n\}$ for $DE(S)$
There exists one substitution σ for every
matrix $M_{n,r}(W)$.

Theorem : The substitution σ_w induced by the finite generating set W of all non-negative integer solutions of $DE(S)$ is a most general AC1-unifier of S .

AC1-Unification

- Corollary: AC1 is *unitary* for elementary unification.
- Fact:
- Every elementary AC1-unification problem has a solution.

AC-Unification

- An (elementary) AC-unification problem S is an AC1-unification problem in which the unit 1 does not occur.
- Any AC-unifier of S is also an AC1-unifier of S .

AC-Unification

- Lemma: The elementary AC-unification problem S is solvable iff the system of homogeneous linear Diophantine equations $DE(S)$ has a solution in the positive integers.
- $S := \{x_1 x_2 = ? x_3^2\}$
- $\Phi := \{x_1 \dashrightarrow x_1 x_2^2, x_2 \dashrightarrow x_1, x_3 \dashrightarrow x_1 x_2\}$

AC-Unification

- Theorem: Solvability of elementary AC-unification problem is decidable in polynomial time.
- This problem can easily be turned into a linear programming problem, which is solvable in polynomial time.
